

# Chapter 10

## **Interrupts**

**Updated: 4/19/19**

# Basic Concepts in Interrupts

- An interrupt is a communication **process** set up in a microprocessor or microcontroller in which:
  - An internal or external device **requests the MPU** to stop the processing
    - The MPU acknowledges the request
    - Attends to the request
    - Goes back to processing where it was interrupted

# Types of Interrupts

## □ Hardware interrupts

- Maskable: can be masked or disabled

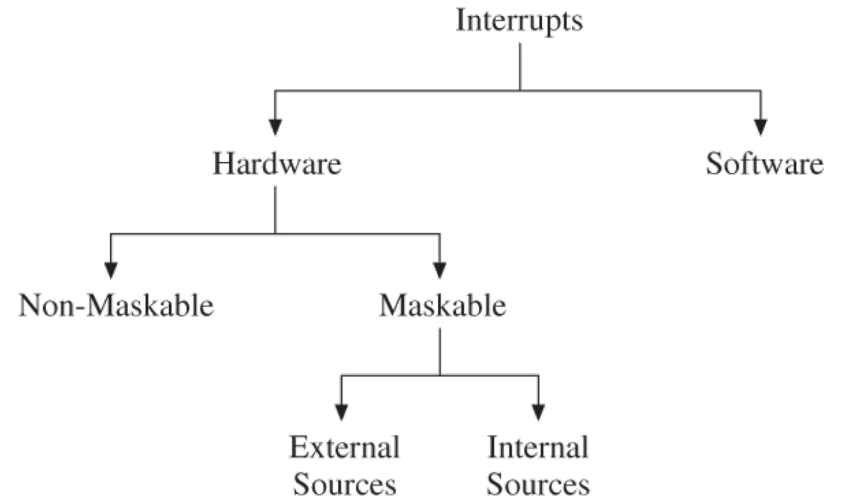

- Two groups: external and internal interrupts

- External through designated I/O pins
- Internal by Timers, A/D, etc.

- Non-maskable: cannot be disabled

## □ Software interrupts: generally used when the situation requires **stop** processing and start all over

- Examples: divide by zero or stack overflow
- Generally, microcontrollers do **not** include software interrupts

# MPU Response to Interrupts (1 of 2)

- When the interrupt process is **enabled**, the MPU, during execution, checks the interrupt request **flag** just before the end of each instruction.
- If the interrupt request is present, the MPU:
  - **Completes** the execution of the instruction
  - **Resets** the interrupt flag
  - **Saves** the address of the program counter on the stack
    - Some interrupt processes also save contents of MPU registers on the stack.
  - **Stops** the execution

# MPU Response to Interrupts (2 of 2)

- ❑ To restart the execution, the MPU needs to be redirected to the memory location where the interrupt request can be met.
  - Accomplished by **interrupt vectors**
- ❑ The set of instructions written to meet the request (or to accomplish the task) is called an **interrupt service routine (ISR)**.
- ❑ Once the request is accomplished, the MPU should find its way back to the instruction, next memory location where it was interrupted.
  - Accomplished by a specific **return** instruction

```
Main code
....
Setup interrupt vectors
....
HERE: GOTO HERE

ORG 0x100
INT1_ISR: ISR code
....
....
RETFIE

END
```

# Interrupt Service Routine (ISR)

## □ RETFIE instruction format

■ RETFIE [s] ;Return from interrupt: s = 0 or 1

□ If s =1, the MPU also retrieves the contents of W, BSR, and STATUS register (previously saved) before enabling the global interrupt bit.

■ Format: RETFIE FAST

□ The same as RETFIE 1 except the formats are different

Main code

....

Setup interrupt vectors

....

HERE: GOTO HERE

ORG 0x100

INT1\_ISR: ISR code

....

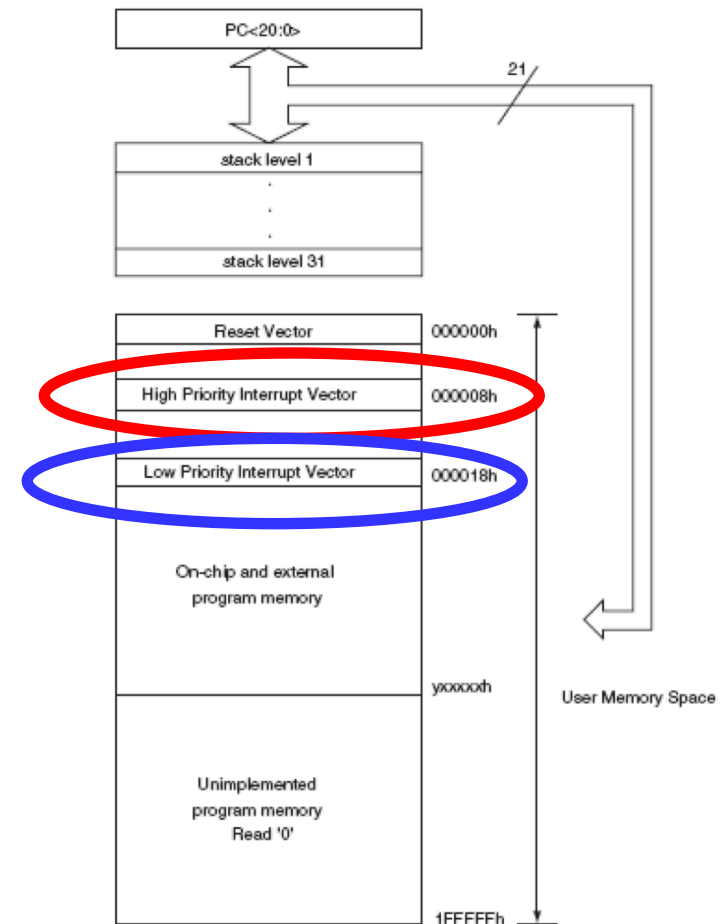

....

RETFIE

END

# Interrupt Vectors

- Direct the MPU to the location where the interrupt request is accomplished.
- They are:
  - Defined memory location where a specific memory location/s is assigned to the interrupt request
  - Defined vector location where specific memory locations assigned to store the vector addresses of the ISRs
  - Specified by external hardware: The interrupt vector address (or a part of it) is provided through external hardware using an interrupt acknowledge signal.

Note, y can be 0 or 1 whereas x can be 0-F

# Interrupt Service Routine (ISR)

- A group of **instructions** that accomplishes the task requested by the interrupting source
- Similar to a subroutine except that the ISR must be terminated in a **Return** instruction specially designed for interrupts
  - The Return instruction, when executed, finds the return address on the stack and redirects the program execution where the program was interrupted.
  - Some Return instructions are designed to retrieve the contents of MPU registers if saved as a part of the interrupts.
  - → RETFIE FAST (1/0)

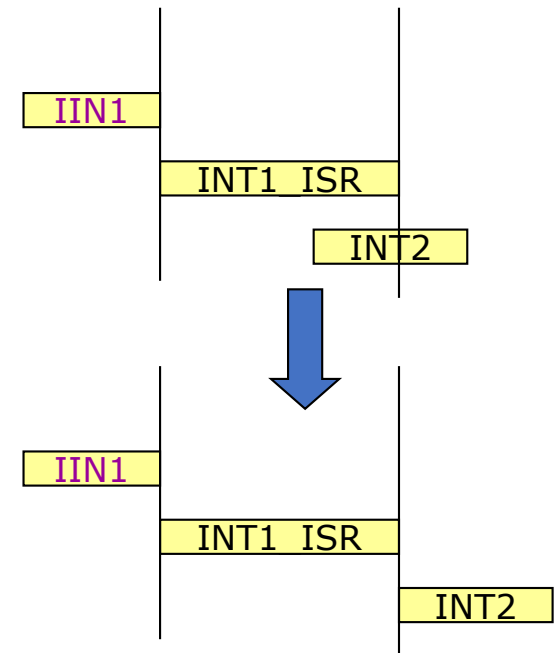

# Interrupt Priorities

## □ Rationale for priorities

- Multiple interrupt sources exist in a system, and more than one interrupt requests can arrive simultaneously.

- Example: A/D and Timer0

- When one request is being served (meaning when the MPU is executing an ISR), another request can arrive.
- → the interrupt requests must be **prioritized**.
- Most MCUs (and MPUs) include an interrupt priority scheme. Some are based on **hardware** and some use **software**.

**INT1 has higher priority than INT2**

# Reset as a Special Purpose Interrupt

- **Reset** is an external signal that enables the processor to **begin** execution or interrupts the processor if the processor is executing instructions.
- There are at least two types of resets in microcontroller-based systems.
  - **Power-on** reset and **manual** reset
- When the reset signal is activated, it establishes or reestablishes the **initial conditions** of the processor and directs the processor to a specific starting memory location.

# PIC18 Interrupts

## □ PIC18 Microcontroller family

- Has multiple **sources** that can send interrupt requests
  - Does not have any non-maskable or software interrupts; all interrupts are maskable (can be disabled)
- Has a **priority** scheme divided into two groups
  - High priority and low priority
- Uses many Special Function Registers (SFRs) to implement the interrupt process

# PIC18 Interrupt Sources

- Divided into two groups
  - External sources and internal peripheral sources on the MCU chip
  - External sources
    - Three pins of PORTB -RB0/INT0, RB1/INT1,and RB2/INT2 (edge driven)
    - Change in logic levels of pins RB4-RB7 of PORTB can be recognized as interrupts
  - Internal sources
    - Use SFRs to setup the interrupt process....

# PIC18 Interrupt Sources

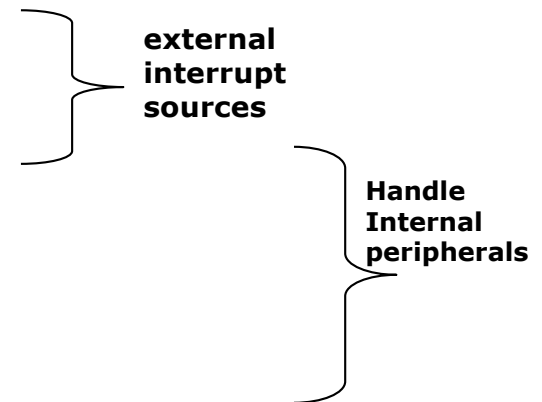

## □ Internal peripheral sources

- Examples: Timers, A/D Converter, Serial I/O, and Low-Voltage Detection Module

## □ SFRs

- Used to setup the interrupt process:

■ RCON	Register Control (global priority)
■ INTCON	Interrupt Control
■ INTCON2	Interrupt Control2
■ INTCON3	Interrupt Control3
■ PIR1 and PIR2	Peripheral Interrupt Register1 & 2
■ PIE1 and PIE2	Peripheral Interrupt Enable 1 & 2
■ IPR1 and IPR2	Interrupt Priority Register 1 & 2

Click here: [Summery of Interrupt Registers](#)

# PIC18 Interrupt Sources

- To recognize the occurrence of an interrupt request, the MPU needs to check the following **three bits**:
  - The **flag** bit to indicate that an interrupt request is present
  - The **enable** bit to redirect the program execution to the interrupt vector address
  - The **priority** bit (if set) to select priority

# PIC18 Interrupt Sources

□ In PIC interrupt are controlled by three bits in three different registers.

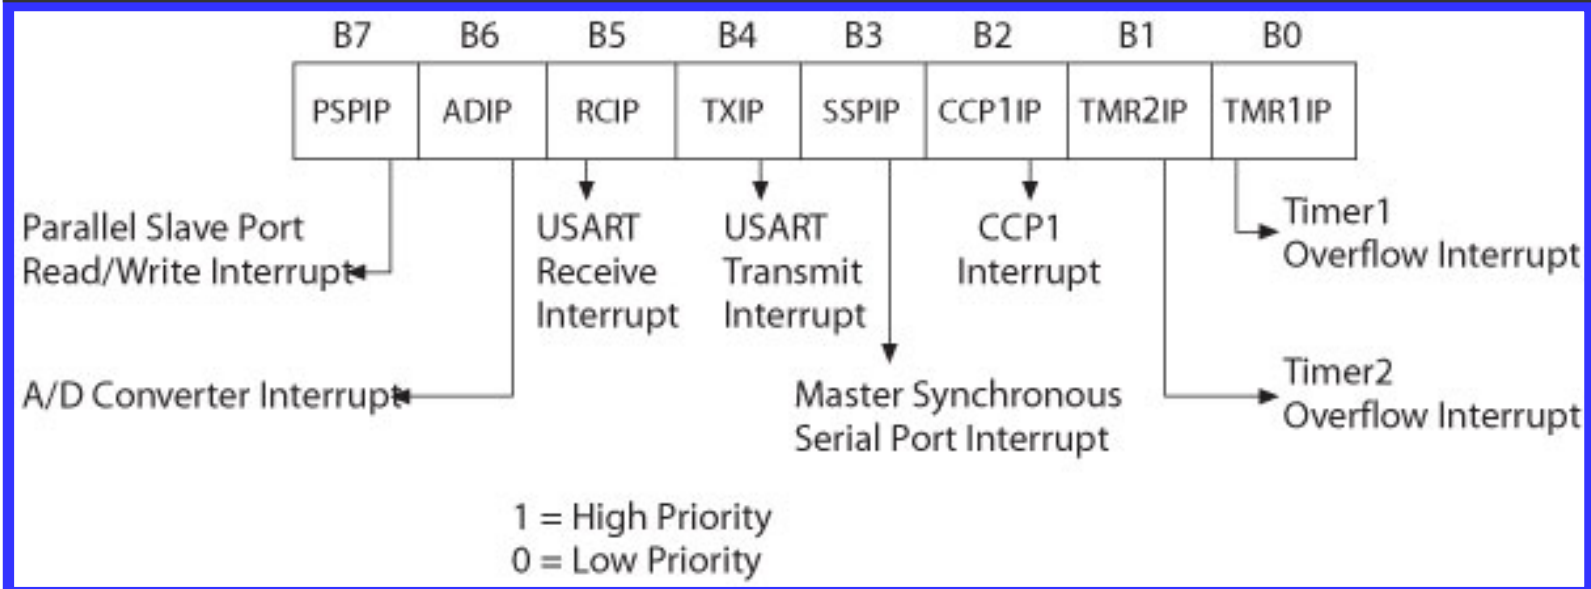

■ The **IE** bit is the interrupt **enable** bit used to enable the interrupt.

■ The **IP** bit is the interrupt priority bit which selects the **priority** (high or low).

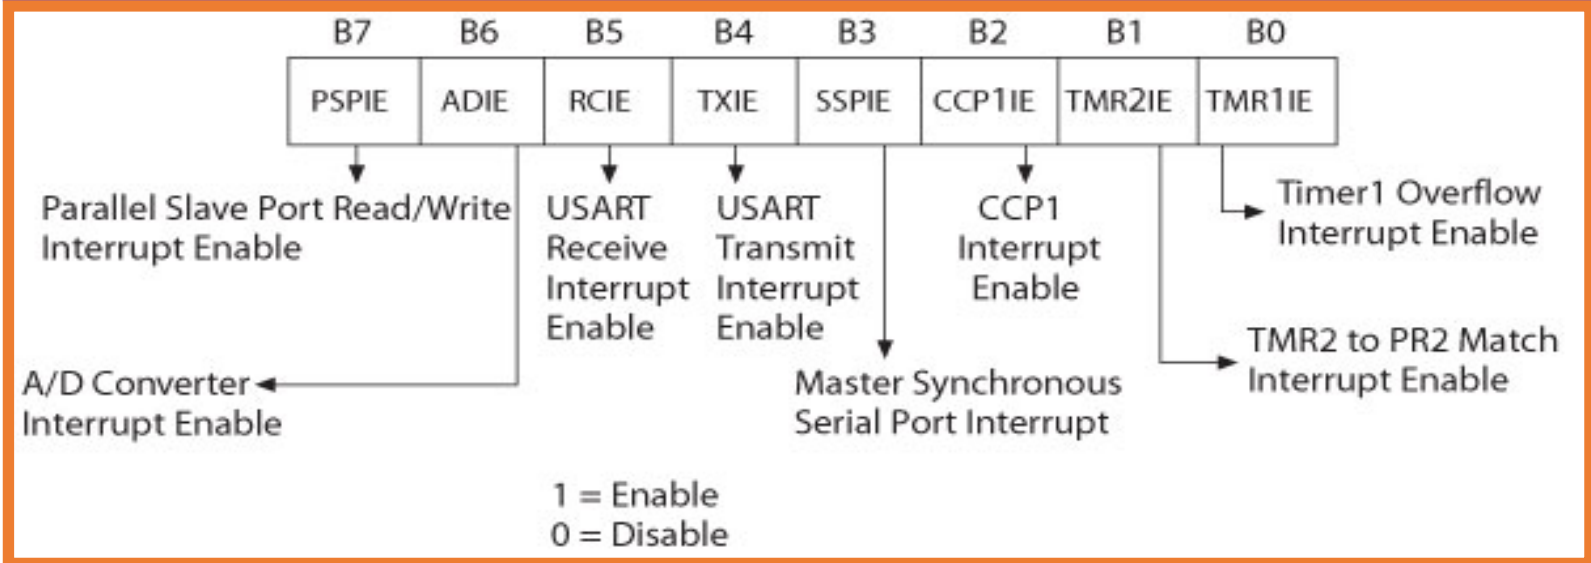

■ The **IF** bit is the interrupt **flag** that indicates the interrupt has occurs. This bit **must be cleared** in the interrupt service function or no future interrupt will ever take effect.

PIR (flag)

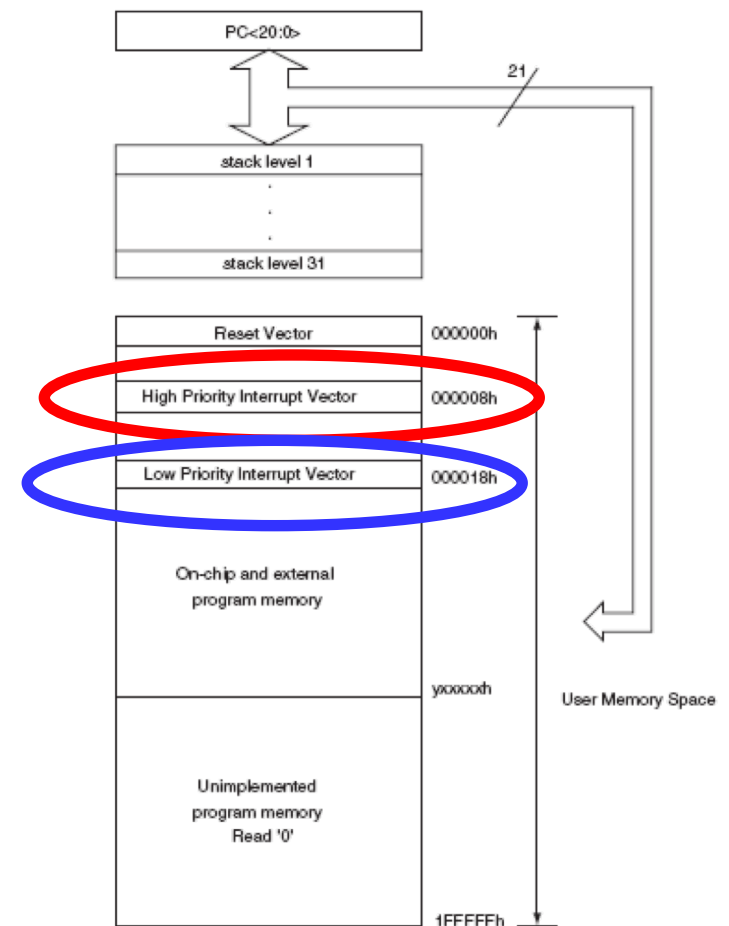

IPR (priority)  
1=High Prio  
0=Low Prio

PIE (peripheral)  
1=Enable  
0=Disable

# Interrupt Priorities and RCON Register (1 of 2)

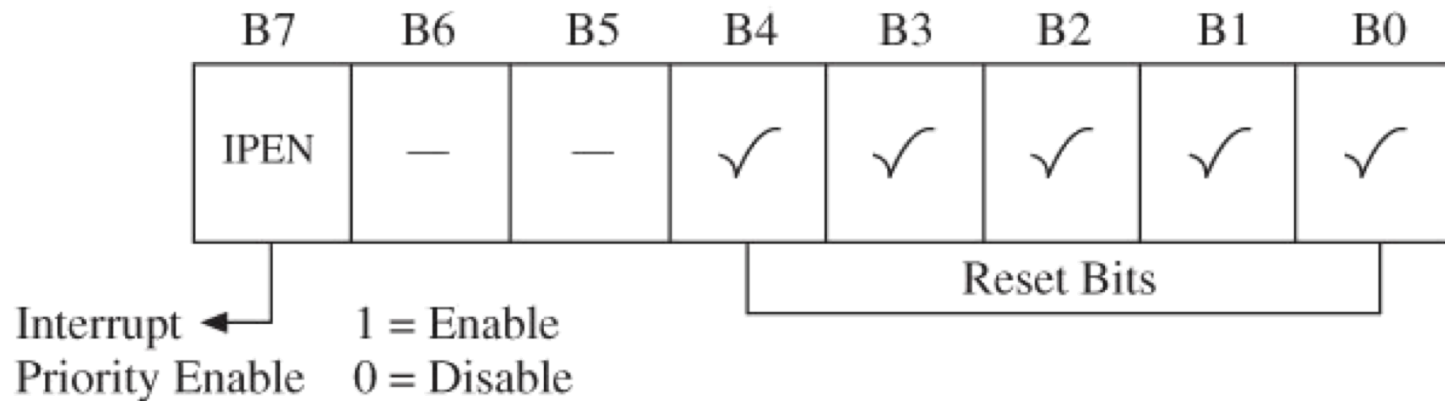

- Any interrupt can be set up as high-priority or low-priority.
  - All high-priority interrupts are directed to the interrupt vector location **000008H**.
  - All low-priority interrupts are directed to the interrupt vector location **000018H**.
  - A high-priority interrupt can interrupt a low-priority interrupt in progress.

Note. y can be 0 or 1 whereas x can be 0-F

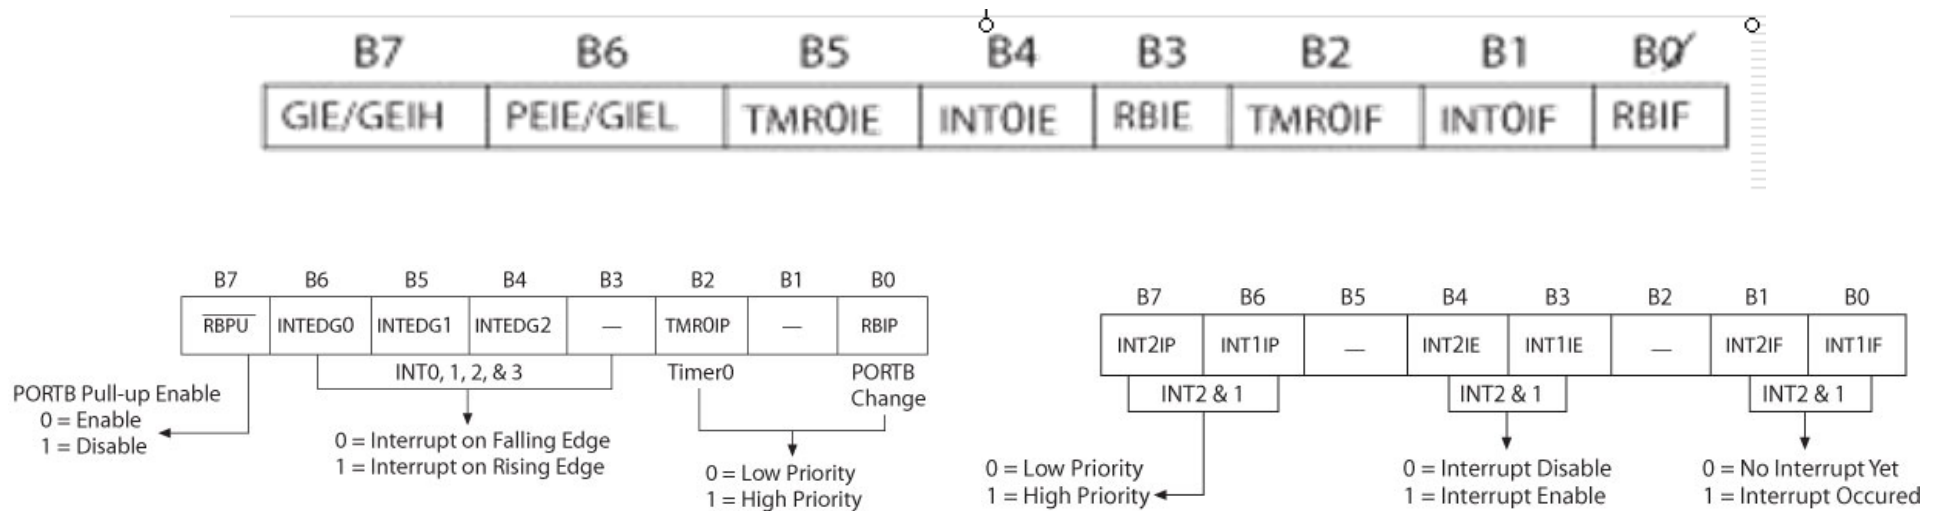

# Interrupt Priorities and RCON Register (2 of 2)

- The interrupt priority feature is enabled by Bit7 (IPEN) in RCON register.

# External Interrupts and INTCON Registers (1 of 3)

- Three registers with interrupt bit specifications primarily for external interrupt sources. INTCON (3)

# Example

□ Write an instruction to setup INT1 as the high priority interrupt. (INT1 → RB1)

## High Priority Interrupt Vector:

5	0008	EF80	GOTO 0x100
6	000A	F000	NOP
7	000C	8ED0	BSF 0xfd0, 0x7, ACCESS
8	000E	8EF2	BSF 0xff2, 0x7, ACCESS
9	0010	9AF1	BCF 0xff1, 0x5, ACCESS
10	0012	8CF0	BSF 0xff0, 0x6, ACCESS
11	0014	86F0	BSF 0xff0, 0x3, ACCESS
12	0016	0E0A	MOVLW 0xa
13	0018	6E01	MOVWF 0x1, ACCESS
14	001A	FFFF	NOP

## ISR:

129	0100	0601	DECF 0x1, F, ACCESS
130	0102	E102	BNZ 0x108
131	0104	0E0A	MOVLW 0xa
132	0106	6E01	MOVWF 0x1, ACCESS
133	0108	0011	RETFIE 0x1
134	010A	FFFF	NOP

```

ORG 0x00
GOTO MAIN

ORG 0x0008
GOTO INT1_ISR

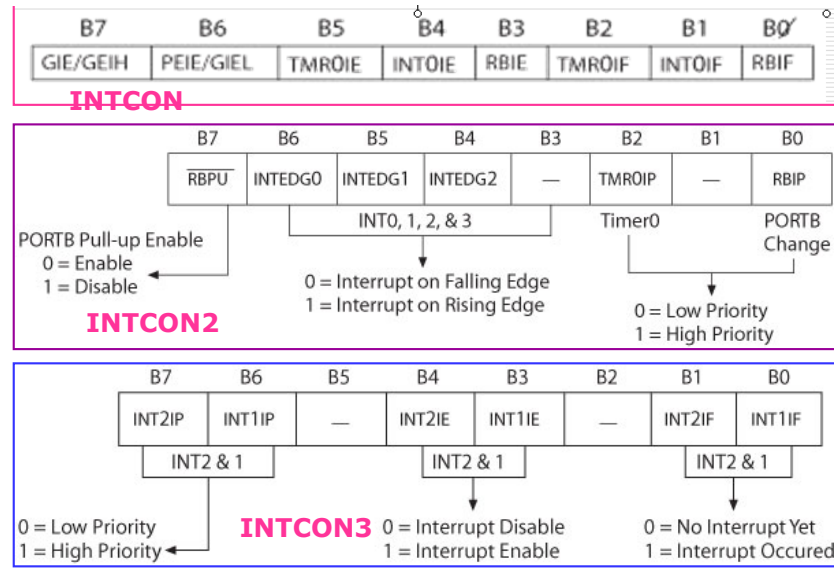

MAIN: BSF RCON, IPEN
      BSF INTCON, GIEH
      BCF INTCON2, INTEDG1
      BSF INTCON3, INT1IP
      BSF INTCON3, INT1IE
      MOVLW D'10'
      MOVWF REG1,0
HERE: GOTO HERE

      MOVWF REG1,0
GOBACK: RETFIE FAST
      END
  
```

# Example

## Software Setting

```

ORG    0x00
GOTO  MAIN

ORG    0x0008
GOTO  INT1_ISR

MAIN:  BSF    RCON,    IPEN
       BSF    INTCON, GIEH
       BCF    INTCON2, INTEDG1
       BSF    INTCON3, INT1IP
       BSF    INTCON3, INT1IE
       MOVLW D'10'
       MOVWF  REG1,0
HERE:  GOTO  HERE

INT1_ISR
ORG    0x100
DECF   REG1,1,0
BNZ    COBACK
MOVLW  D'10'
MOVWF  REG1,0
COBACK: RETFIE FAST
END
    
```

If ZERO no priority (early versions)

If enabled → high priority → gates all H/L interrupts to the CPU (remember: GIEL enables all low-priorities Interrupts to the CPU)

If 1 → rising edge (RB1)

If 1 → High Priority

If 1 → INT1 enabled

When INT1 goes from high to low value of REG1 decrements!

NOTE: INTCON3: FLAG bit is read only!

**Convert to C code!**

# Interrupt Setting (INT0 high priority only)

Name	Priority Bit	Local Enable Bit	Local Flag Bit
INT0 external interrupt	*	INTCON,INT0IE	INTCON,INT0IF
INT1 external interrupt	INTCON3,INT1IP	INTCON3,INT1IE	INTCON3,INT1IF
INT2 external interrupt	INTCON3,INT2IP	INTCON3,INT2IE	INTCON3,INT2IF
RB port change interrupt	INTCON2,RBIP	INTCON,RBIE	INTCON,RBIF
TMR0 overflow interrupt	INTCON2,TMR0IP	INTCON,TMR0IE	INTCON,TMR0IF
TMR1 overflow interrupt	IPR1,TMR1IP	PIE1,TMR1IE	PIR1,TMR1IF
TMR3 overflow interrupt	IPR2,TMR3IP	PIE2,TMR3IE	PIR2,TMR3IF
TMR2 to match PR2 int.	IPR1,TMR2IP	PIE1,TMR2IE	PIR1,TMR2IF
CCP1 interrupt	IPR1,CCP1IP	PIE1,CCP1IE	PIR1,CCP1IF
CCP2 interrupt	IPR2,CCP2IP	PIE2,CCP2IE	PIR2,CCP2IF
A/D converter interrupt	IPR1,ADIP	PIE1,ADIE	PIR1,ADIF
USART receive interrupt	IPR1,RCIP	PIE1,RCIE	PIR1,RCIF
USART transmit interrupt	IPR1,TXIP	PIE1,TXIE	PIR1,TXIF
Sync. serial port int.	IPR1,SSPIP	PIE1,SSPIE	PIR1,SSPIF
Parallel slave port int.	IPR1,PSPIP	PIE1,PSPIE	PIR1,PSPIF
Low-voltage detect int.	IPR2,LVDIP	PIE2,LVDIE	PIR2,LVDIF
Bus-collision interrupt	IPR2,BCLIP	PIE2,BCLIE	PIR2,BCLIF

# C Code Example

When a pulse is generated on INT0 the high priority interrupt is generated!

```
ADCON1 = 0x0F; // make ports pins digital

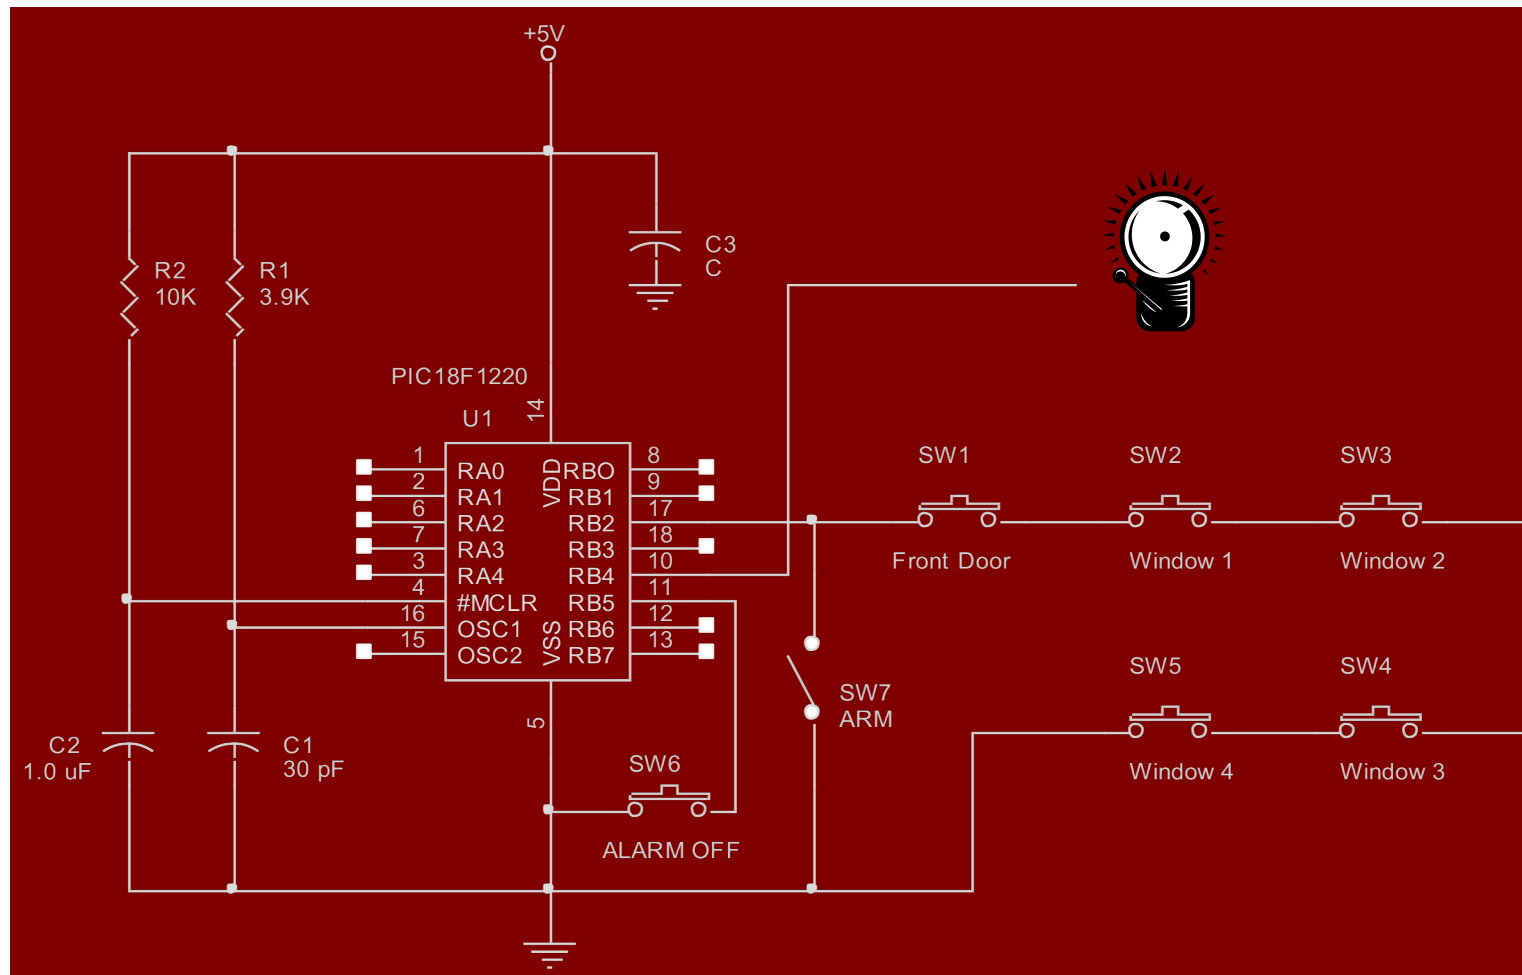

TRISB = 1; // make RB0 input

RCONbits.IPEN = 1; // IPEN = 1

INTCON2bits.INTEDG0 = 0; // make INT0 negative edge triggered
INTCONbits.INT0IE = 1; // enable INT0
INTCONbits.GIEH = 1; // enable high priority interrupts

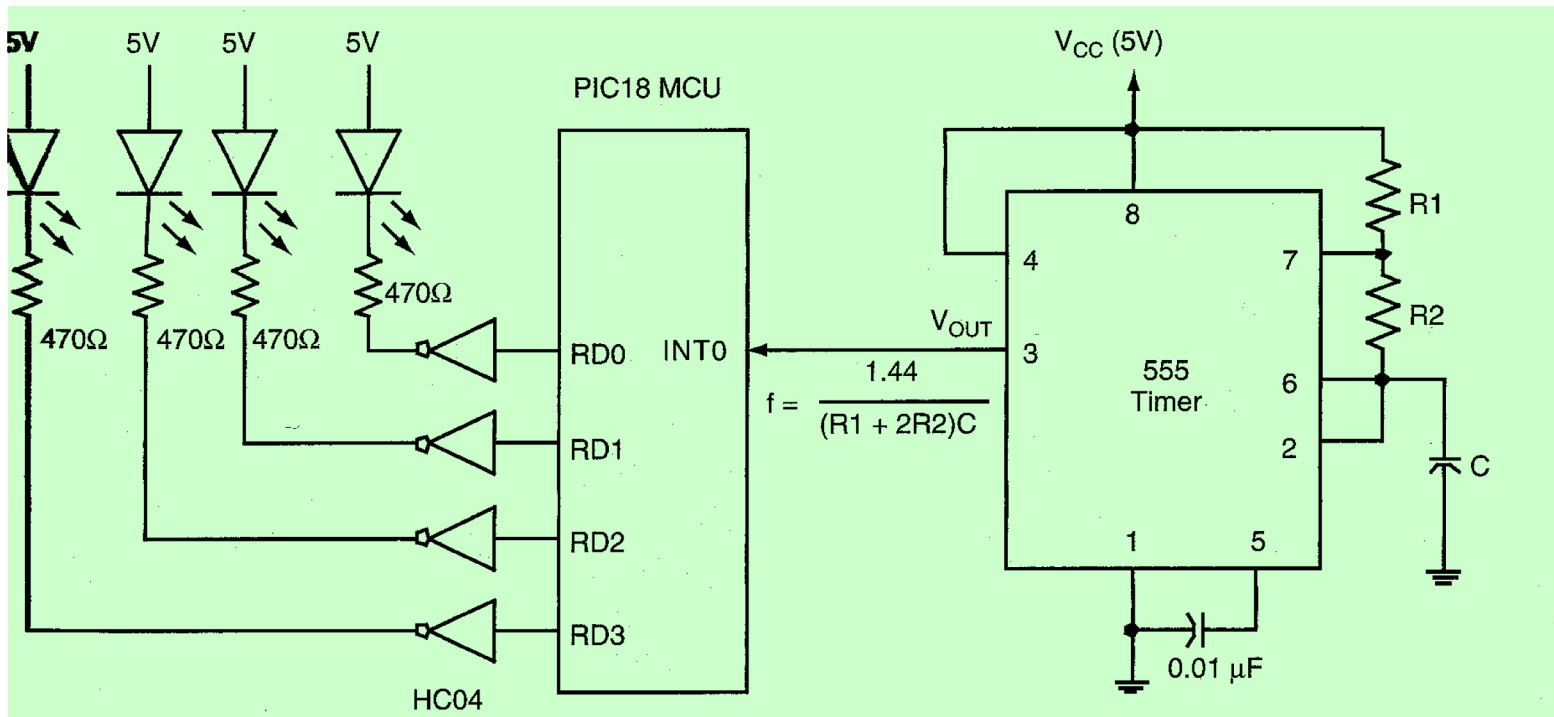

// INT0 is now armed and active
```

# C Code Example – Burglar Alarm Circuit

# Another practical Example

Suppose you are given a circuit as shown below. Write a main program and an INTO0 interrupt service routine in assembly language. The main program initializes a counter to 0, enables the INTO0 interrupt, and then stays in a while-loop to wait forever. The INTO0 interrupt service routine simply increments the counter by 1 and outputs it to the LEDs. Whenever is incremented to 15, the service routine resets it to 0. Choose appropriate component that the PIC18 receives an INTO0 interrupt roughly every second.

# Handling Multiple Interrupt Sources

- In PIC18 MCU, all interrupt requests are directed to one of two memory locations:
  - 000008H (high-priority) or 000018 (low-priority)
- When multiple requests are directed to these locations, the interrupt source must be identified by checking the interrupt flag through software instructions.

# Example

```
BSF    INTCON, GIEL           ;Enable global low-priority - INTCON ,6>
BCF    IPR1, TMR1IP         ;Set Timer1 as low-priority
BSF    PIE1, TMR1IE        ;Enable Timer1 overflow interrupt
BCF    IPR1, TMR2IP        ;Set Timer2 as low-priority
BSF    PIE1, TMR2IE        ;Enable Timer2 match interrupt
```

```
BCF    PIR1, TMR1IF        ;Clear TMR1 flag
CALL   TMR1L               ;Call service subroutine
```

```
BCF    PIR1, TMR2IF        ;Clear TMR2 flag
CALL   TMR2                ;Call service subroutine
```

Name	Priority Bit	Local Enable Bit	Local Flag Bit
KB port change interrupt	INTCON2,KBIF	INTCON,KBIE	INTCON,KBIF
TMR0 overflow interrupt	INTCON2,TMR0IP	INTCON,TMR0IE	INTCON,TMR0IF
TMR1 overflow interrupt	IPR1,TMR1IP	PIE1,TMR1IE	PIR1,TMR1IF
TMR3 overflow interrupt	IPR2,TMR3IP	PIE2,TMR3IE	PIR2,TMR3IF
TMR2 to match PR2 int.	IPR1,TMR2IP	PIE1,TMR2IE	PIR1,TMR2IF

# Example of using multiple interrupts

INT1=High Priority / TMR1 and TMR2 Low Priority

Assign the High Priority Interrupt Vector

Assign the Low Priority Interrupt Vector

Setup the interrupt registers for external  
interrupt

Setup the interrupt registers for internal  
interrupts

```

# XC8 Interrupt Handling

```
void __interrupt("high_priority") CheckButtonPressed(){
    int k=0;
    if(INTCONbits.INT0IF){
        for(k=0;k<10;k++){
            PORTDbits.RD0=!PORTDbits.RD0;
            __delay_ms(1000);
        }
        INTCNbits.INT0IF=0;
        PORTDbits.RD0=0;
    }
}
```

With in the Interrupt definition  
It is important to clear the  
Interrupt FLAG!

The ISR can be defined as  
high\_priority or low\_priority

This **Interrupt Vector** is called  
CheckButtonPressed  
The ISR for IV is defined here

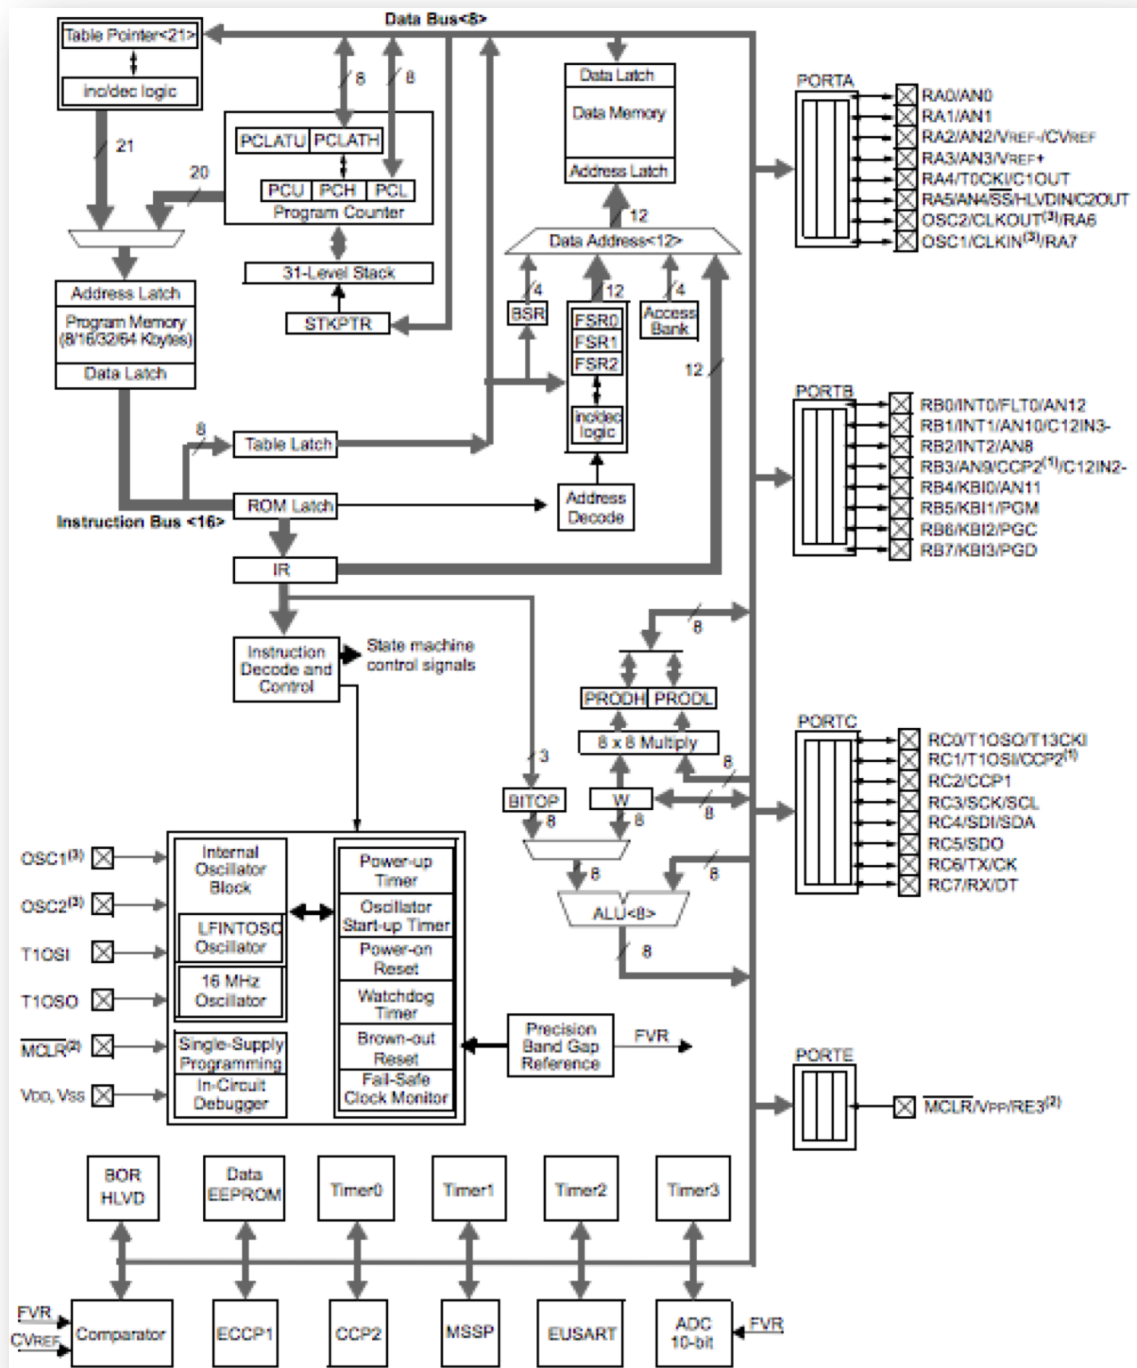

```
void main(void) {
    ANSELH = 0x00; //Set RB<4:0> as digital I/O pins
    INTCN2bits.RBPU = 1; // Port B pull-ups on
    TRISD = 0x0; //set port D as output

    ADCON1 = 0x0F; // make ports pins digital
    TRISB = 1; // make RB0 input
    RCONbits.IPEN = 1; // IPEN = 1
    INTCN2bits.INTEDG0 = 1; // make INT0 negative edge triggered
    INTCNbits.INT0IE = 1; // enable INT0
    INTCNbits.GIEH = 1; // enable high priority interrupts
    // INT0 is now armed and active
    INTCNbits.INT0IF = 0;

    PORTDbits.RD1 = 1; // pin 19
    __delay_ms(500);
    PORTDbits.RD1 = 0;

    while(1)
    {
        asm ("NOP");
    }
}
```

# PIC18F2XK20 (28-PIN) BLOCK DIAGRAM

# SLEEP and WDT

The SLEEP mode can reduce the power!  
 The CLRWDT is used to reset the WDT  
 Refer to the SPEC sheet.

```
#define ON          1
#define OFF        0
#define LED_0      PORTDbits.RD0
#define LED_1      PORTDbits.RD1
```

```
while(1)
{
    //SLEEP();
    asm ("SLEEP");
    LED_0 = ON;
    __delay_ms(500);
    LED_0 = OFF;
    asm ("CLRWDT");
    LED_1 = ON;
    __delay_ms(2000);
}
```

# PIC18 Resets

- When the reset signal is activated:
  - The MPU goes into a reset state during which the **initial conditions** are established.
  - The program **counter is cleared** to 000000 which is called the reset vector.
  - The MPU begins the execution of instructions from location 000000.

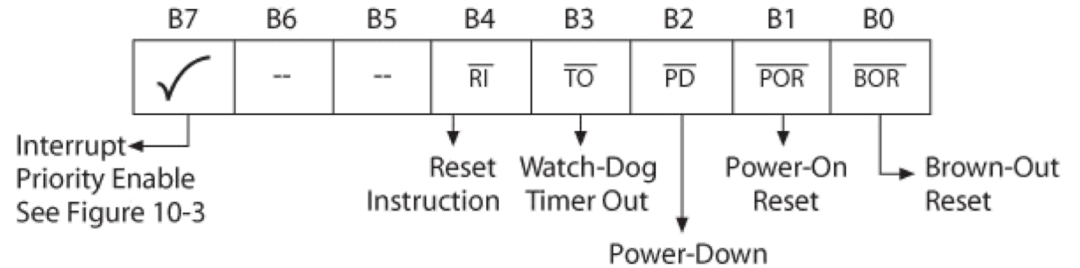

# On Chip reset circuit for PIC18

- Power-on reset (POR)
- $\overline{\text{MCLR}}$  pin reset during normal operation
- $\overline{\text{MCLR}}$  pin reset during SLEEP
- Watchdog timer (WDT) reset (during normal operation)
- Programmable brown-out reset (BOR)
- RESET instruction
- Stack full reset
- Stack underflow reset

# PIC18 Resets

□ PIC18 MCU can be reset by external source such as the push-button key, or when power is turned-on, or by various internal sources.

■ Resets categorized as follows:

- External Manual Reset Key
- Power-on Reset (POR)
- Watchdog Timer Reset (WDT)
- Programmable Brown-Out Reset (BOR)
- RESET and SLEEP Instructions
- Stack Full and Underflow Reset

Find MCLR pin!

# Example of Reset Programming

- Identifying a power-on reset
- `IF_RCON,NOT_POR == 0 ;POR has occurred`
- `setf RCON` ;Reinitialize all reset flags after power on
- <take action particular to power—on reset>
- `ENDIF_`
- Identifying a reset due to execution of a “reset” instruction
- `IF_RCON,NOT_RI == 0 ;reset' instruction has been executed`
- `bsf RCON.NOT_RI` ;Set bit to distinguish froe other resets
- <take appropriate action in response to “reset” instruction>
- `ENDIF`
